AB BACKGROUND: AMP-activated protein kinase (AMPK) regulatory
gamma2 subunit (PRKAG2) mutations cause a human cardiomyopathy
with cardiac hypertrophy, preexcitation, and glycogen deposition. PRKAG2
cardiomyopathy is recapitulated in transgenic mice overexpressing mutant
PRKAG2 N488I in the heart (TGgamma2N488I). AMPK is a
heterotrimeric kinase consisting of 1 catalytic (alpha) and 2 regulatory
(beta and gamma) subunits. Two alpha-subunit isoforms, alpha1
and alpha2, are expressed in the heart; however, the contribution of
AMPK utilization of these subunits to PRKAG2 cardiomyopathy is
unknown. Mice overexpressing a dominant-negative alpha2 subunit of
AMPK (TGalpha2DN) provide a tool for selectively inhibiting
alpha2, but not alpha1, subunit-associated AMPK activity.
METHODS AND RESULTS: In compound-heterozygous TGgamma2N488I/TGalpha2DN
mice, AMPK activity associated with alpha2 but not alpha1 was
decreased compared with TGgamma2N488I. The TGalpha2DN transgene reduced
the disease phenotype of TGgamma2N488I, partially or completely
normalizing the ECG, cardiac function, cardiac morphology, and exercise
capacity in compound-heterozygous mice. TGgamma2N488I hearts had normal
resting levels of high-energy phosphates and could improve cardiac
performance during exercise. Cardiac glycogen content decreased in

TGgamma2N488I mice after exercise stress, indicating availability of the stored glycogen for metabolic utilization. No differences in glycogen-metabolizing enzymes were observed. CONCLUSIONS: The PRKAG2 N488I mutation causes inappropriate AMPK activation, which leads to glycogen accumulation and conduction system disease. The accumulated glycogen can serve as an energy source, and the animals have contractile reserve during exercise. Because the dominant-negative alpha2 subunit attenuates the mutant PRKAG2 phenotype, AMPK complexes containing the alpha2 rather than the alpha1 subunit are the primary mediators of the effects of PRKAG2 mutations.

AB Naturally occurring mutations in the regulatory gamma-subunit of 5'-AMP-activated protein kinase (AMPK) can result in pronounced pathological changes that may stem from increases in muscle glycogen levels, making it critical to understand the role(s) of the gamma-subunit in AMPK function. In this study we cloned the mouse AMPKgamma3 subunit and revealed that there are two transcription start sites, which result in a long form, gamma3L (AF525500) and a short form, gamma3S (AF525501). AMPKgamma3L is the predominant form in mouse and is specifically expressed in mouse skeletal muscle at the protein level. In skeletal muscle, AMPKgamma3 shows higher levels of expression in fast-twitch white glycolytic muscle (type IIb) compared with fast-twitch red oxidative glycolytic muscle (type IIa), whereas gamma3 is undetectable in soleus muscle, a slow-twitch oxidative muscle with predominantly type I fibers. AMPKgamma3 can coimmunoprecipitate with both alpha and beta AMPK subunits. Overexpression of gamma3S and gamma3L in mouse tibialis anterior muscle in vivo has no effect on alpha1 and alpha2 subunit expression and does not alter AMPKalpha2 catalytic activity. However, gamma3S and gamma3L overexpression significantly increases AMPKalpha1 phosphorylation and activity by approximately 50%. The increase in AMPKalpha1 activity is not associated with alterations in glycogen accumulation or glycogen synthase expression. In conclusion, the gamma3 subunit of AMPK is highly expressed in fast-twitch glycolytic skeletal muscle, and wild-type gamma3 functions in the regulation of alpha1 catalytic activity, but it is not associated with changes in muscle glycogen concentrations.

AB The AMP-activated protein kinase (AMPK) system was first
discovered 30 years ago. Since that time, knowledge of the diverse
physiological functions of AMPK has grown rapidly and continues
to evolve. Most recently, the observation that spontaneously occurring
genetic mutations in the gamma regulatory subunits of
AMPK give rise to a skeletal and cardiac muscle disease emphasizes
the critical importance of AMPK in the maintenance of health and
disease. The cardiac phenotype observed in humans harbouring
genetic mutations in the gamma 2 regulatory subunit (PRKAG2) of
AMPK is consistent with abnormal glycogen
accumulation in the heart. The perturbation of AMPK
activity induced by genetic mutations in PRKAG2 and the resultant effect
on muscle cell glucose metabolism may be relevant to the issue
of targeting AMPK in drug development for insulin-resistant
diabetes mellitus.

AB AMP-activated protein kinase (AMPK) is the downstream component
of a protein kinase cascade that plays a key role in the regulation of
energy metabolism. In humans, mutations in the .
gamma.2-subunit of AMPK cause cardiac hypertrophy
associated with Wolff-Parkinson-White syndrome, characterized by

ventricular preexcitation. The effect of these mutations on AMPK activity and in development of the disease is enigmatic. Here we report that transgenic mice with cardiac-specific expression of .gamma.2 harboring a mutation of arginine residue 531 to glycine (RG-TG) develop a striking cardiac phenotype by 4 wk of age, including hypertrophy, impaired contractile function, electrical conduction abnormalities, and marked glycogen accumulation. At this stage, AMPK activity isolated from hearts of RG-TG mice was almost completely abolished but could be restored after phosphorylation by an upstream AMPK kinase. At 1 wk of age, there was no detectable evidence of a cardiac phenotype, and AMPK activity in RG-TG hearts was similar to that in nontransgenic, control mice. We propose that mutations in .gamma.2 lead to suppression of total cardiac AMPK activity secondary to increased glycogen accumulation. The subsequent decrease in AMPK activity provides a mechanism that may explain the development of cardiac hypertrophy in this model. Copyright .COPYRGT. 2006 the American Physiological Society.

AB The AMP-activated protein kinase (AMPK) is the downstream component of a kinase cascade that acts as a sensor of cellular energy status. Falling ATP causes a large rise in AMP due to the action of adenylate kinase. AMP activates (and ATP inhibits) via allosteric effects and by stimulating phosphorylation of the kinase domain on the α subunit by upstream kinase(s). The major upstream kinase is a complex containing the tumor suppressor, LKB1, although there are indications that others exist. LKB1, which also lies upstream of a family of 11 AMPK-related kinases, is constitutively active, but AMP binding to AMPK makes it a better substrate for LKB1. There are two binding sites for AMP and ATP on the γ subunit of AMPK, which bind the nucleotides with positive co-operativity. Binding of AMP to the N-terminal site causes a conformational change that prevents a pseudosubstrate sequence from inhibiting the kinase domain on the α subunit. Point mutations in the AMP-binding sites of the γ 2 isoform cause hereditary cardiac arrhythmias. They interfere with AMP and ATP binding but also increase the basal phosphorylation by LKB1, and thus the basal activity. This causes excessive glycogen accumulation, and the arrhythmias appear to be a secondary consequence of this. AMPK has many downstream targets and when activated it switches on ATP-producing catabolic pathways while switching off ATP-consuming processes. One recently identified target is TSC2, via which AMPK has a major influence on cell growth by inhibiting the TOR pathway. As well as regulating energy balance at the cellular level, AMPK also performs this task at the whole body level, by mediating the effects of adipokines and gut hormones such as leptin, adiponectin, resistin and ghrelin. AMPK is also involved in sensing hypoxia at the whole body level, via actions in the carotid body and pulmonary arteries.

AB It has been shown that excessive glycogen accumulation contributes to the development of the hypertrophic cardiomyopathy linked to mutations in gamma 2 AMPK subunit. Transgenic mice (TG) with cardiac-specific overexpression of mutant (N488I) gamma 2 AMPK subunit mimic the human disease, but the mechanism of glycogen accumulation in these hearts is not known. We tested the hypothesis that mutation of gamma 2 AMPK subunit causes a decrease of glucose utilization leading to glycogen accumulation. Isolated hearts from WT and TG groups were perfused in Langendorff mode with Krebs-Henseleit buffer containing C-13 labeled substrates (mM): 0.4 mixed fatty acids, 1 lactate, 0.19 beta-hydroxybutyrate, 5.5 glucose and 50 mu U/ml insulin. 13C NMR spectroscopy and oxygen consumption were used to measure glycolytic flux and substrate oxidation rates. 2-deoxyglucose uptake was measured using P-31 NMR spectroscopy. Isovolumic contractile function was estimated as rate pressure product (RPP). Table (n=6-15 in each group) shows the results. TG hearts showed significant hypertrophy with 5-fold higher glycogen content than WT. RPP was decreased by 20%, Glucose uptake was markedly increased (2-fold) while glycolytic flux and glucose oxidation were decreased (7 and 2 fold, respectively). Thus, it is likely that this discoordination of glucose uptake and utilization results in glycogen accumulation that contributes to cardiac hypertrophy and functional deterioration in hearts with mutations in gamma 2 AMPK subunit. AB The invention provides cDNA mols. encoding various muscle-specific adenosine monophosphate-activated protein kinase (AMPK) . gamma. subunits isolated from human and Sus scrofa. The invention also provides: (1) primers and probes specific for said cDNA mols.; (2) recombinant vectors comprising said cDNA mols.; and (3) host cells and/or animals transformed with said vectors. The invention further provides mutants of the S. scrofa AMPK .gamma. subunit, which involve an arginine->glutamine substitution at position 41, and/or a valine->isoleucine substitution at position 40. Still further, the invention provides genotyping techniques using, such as polymerase chain reaction (PCR), restriction fragment length polymorphism (RFLP), and nucleic acid hybridization for detection of a metabolic disorder (such as altered glycogen accumulation) in pigs, resulting from a mutation in the AMPK .gamma. subunit gene using said primers and/or probes. The invention relates that the mol. genetic techniques can also be used to detect single nucleotide polymorphisms in the AMPK . gamma. subunit gene. Finally, the invention provides for the use of said transformed cells, transgenic and/or knockout animals for screening compds. able to modulate AMPK activity. The cDNA sequences, as well as the corresponding amino acid sequences of various forms of AMPK .gamma. subunits from human and S. scrofa are provided. The invention designated PRKAG3 as the gene encoding the muscle-specific AMPK .gamma. subunit, and provides evidence that PRKAG3 is identical to the RN gene, a gene found associated with high muscular content of glycogen. The invention also provides evidence that the R41Q substitution is most likely the causative mutation in RN- animals which have an increase in muscle glycogen. The invention also discussed how identification of the RN- allele, or mutations in the PRKAG3, gene can be used to improve meat quality and/or breeding in the pig industry.

ABSTRACT IS AVAILABLE IN THE ALL AND IALL FORMATS

AB 5'-AMP-activated protein kinase (AMPK) is important for
metabolic sensing. We used AMPK gamma 3
mutant-overexpressing Tg-Prkag3(225Q) and AMPK
gamma 3-knockout Prkag3(-/-) mice to determine the role
of the AMPK gamma 3 isoform in exercise-induced
metabolic and gene regulatory responses in skeletal muscle. Mice were
studied after 2 h swimming or 2.5 h recovery. Exercise increased basal
and insulin-stimulated glucose transport, with similar responses among
genotypes. In Tg-Prkag3(225Q) mice, acetyl-CoA carboxylase
(ACC) phosphorylation was increased and triglyceride content was reduced
after exercise, suggesting that this mutation promotes greater reliance on
lipid oxidation. In contrast, ACC phosphorylation and triglyceride
content was similar between wild-type and Prkag3(-/-) mice.
Expression of genes involved in lipid and glucose metabolism was altered
by genetic modification of AMPK gamma 3. Expression
of lipoprotein lipase 1, carnitine palmitoyl transferase 1b, and
3-hydroxyacyl-CoA dehydrogenase was increased in Tg-Prkag3(225Q)
mice, with opposing effects in Prkag3(-/-) mice after exercise.
GLUT4, hexokinase 11 (HKII), and glycogen synthase mRNA expression was
increased in Tg-Prkag3(225Q) mice after exercise. GLUT4 and
HKII mRNA expression was increased in wild-type mice and blunted in
Prkag3(-/-) mice after recovery. In conclusion, the
Prkag3(225Q) mutation, rather than presence of a functional
AMPK gamma 3 isoform, directly promotes metabolic and
gene regulatory responses along lipid oxidative pathways in skeletal
muscle after endurance exercise.

AB AIMS/HYPOTHESIS: AMP-activated protein kinase (AMPK) regulates
metabolic adaptations in skeletal muscle. The aim of this study was to
investigate whether AMPK modulates the expression of skeletal
muscle genes that have been implicated in lipid and glucose metabolism
under fed or fasting conditions. METHODS: Two genetically modified animal
models were used: AMPK gamma3 subunit knockout mice (Prkag3(-/-)) and skeletal muscle-specific transgenic mice (Tg-Prkag3(225Q)) that express a mutant (R225Q) gamma3 subunit. Levels of mRNA transcripts of genes involved in lipid and glucose metabolism in white gastrocnemius muscles of these mice (under fed or 16-h fasting conditions) were assessed by quantitative real-time PCR. RESULTS: Wild-type mice displayed a coordinated increase in the transcription of skeletal muscle genes encoding proteins involved in lipid/oxidative metabolism (lipoprotein lipase, fatty acid transporter, carnitine palmitoyl transferase-1 and citrate synthase) and glucose metabolism (glycogen synthase and lactate dehydrogenase) in response to fasting. In contrast, these fasting-induced responses were impaired in Prkag3(-/-) mice. The transcription of genes involved in lipid and oxidative metabolism was increased in the skeletal muscle of Tg-Prkag3(225Q) mice compared with that in wild-type mice. Moreover, the expression of the genes encoding hexokinase II and 6-phosphofructokinase was decreased in Tg-Prkag3(225Q) mice after fasting. CONCLUSIONS/INTERPRETATION: AMPK is involved in the coordinated transcription of genes critical for lipid and glucose metabolism in white glycolytic skeletal muscle.

ABSTRACT IS AVAILABLE IN THE ALL AND IALL FORMATS

AB Expression patterns of the three isoforms of the regulatory gamma-subunit of AMP-activated protein kinase (AMPK) were determined in various tissues from adult humans, mice, and rats, as well as in human primary muscle cells. Real-time PCR-based quantification of mRNA showed similar expression patterns in the three species and a good correlation with protein expression in mice and rats. The gamma3-isoform appeared highly specific to skeletal muscle, whereas gamma1 and gamma2 showed broad tissue distributions. Moreover, the proportion of white, type IIb fibers in the mouse and rat muscle samples, as indicated by real-time PCR quantification of Atp1b2 mRNA, showed a strong positive correlation with the expression of gamma3. In samples of white skeletal muscle, gamma3 clearly appeared to be the most abundant gamma-isoform. Differentiation of human primary muscle cells from myoblasts into multinucleated myotubes was accompanied by upregulation of gamma3 mRNA expression, whereas levels of gamma1 and gamma2 remained largely unchanged. However, even in these cultured myotubes, gamma2 was the most highly expressed isoform, indicating a considerable difference compared with adult skeletal muscle. Immunoblot analysis of mouse gastrocnemius and quadriceps muscle extracts precipitated with a gamma3-specific antibody showed that gamma3 was exclusively associated with the alpha2- and beta2-subunit isoforms. The observation that the AMPKgamma3 isoform is expressed primarily in white skeletal muscle, in which it is the predominant gamma-isoform, strongly suggests that gamma3 has a key role in this tissue.

AB DERWENT ABSTRACT:
NOVELTY - A transgenic non-human animal having integrated
within its genome a transgene or a nucleic acid encoding an AMP-activated
protein kinase gamma3 subunit or its variant, where the nucleic acid is

operably linked to a regulatory element, is new.

DETAILED DESCRIPTION - The transgene has a nucleotide sequence that hybridizes under stringent hybridization conditions with a nucleic acid having a nucleotide sequence complementary to a fully defined sequence of 1470 base pairs (N1) given in the specification, where the sequence encodes an AMP-activated protein kinase γ 3 subunit or its variant, and where the transgene is operably linked to a promoter that drives expression in skeletal muscle. **INDEPENDENT CLAIMS** are included for the following: (1) an expression construct comprising a regulatory element operably linked to a nucleotide sequence having at least 75% sequence identity to the nucleotide sequence of N1, or a nucleotide sequence encoding a polypeptide having at least 75% sequence identity to a fully defined sequence of 489 amino acids (P1) given in the specification, or its portion, where the regulatory element is capable of mediating expression in skeletal muscle; (2) making a transgenic non-human animal cited above, comprising introducing the expression construct of (1) into an ovum, an embryo, or embryonic stem cells of a non-human animal; and (3) identifying a compound or composition for treating or preventing a disease related to energy metabolism, comprising: (a) administering a test compound or test composition to the transgenic non-human animal cited above, and evaluating the effect of the test compound or test composition on the energy metabolism of the transgenic non-human animal, where the test compound or test composition is identified as effective for the treatment or prevention of the disease related to energy metabolism if energy metabolism is altered; or (b) contacting a test compound or test composition with an organ, a tissue or cells derived from the transgenic non-human animal, and evaluating the effect of the test compound or test composition on the energy metabolism on the organ, tissue or cells, where the test compound or test composition is identified as effective for the treatment or prevention of the disease related to energy metabolism if energy metabolism is altered.

BIOTECHNOLOGY - Preferred Transgenic Animal: The transgenic non-human animal has an elevated glycogen content in skeletal muscle, and is selected from the group of mice, rats, rabbits, cats, dogs and pigs. The transgenic non-human animal is preferably a mouse or a pig. The transgene hybridizes under highly stringent conditions. The nucleic acid comprises a nucleotide sequence encoding a polypeptide having at least 75% sequence identity to the sequence of P1, a fully defined sequence of 489 amino acids (P2) given in the specification, or to a fragment of P1 or P2 at least 200 amino acids in length. The nucleic acid encodes a polypeptide having the amino acid sequence of P1 or P2, or an R225Q variant of the sequence of P1 or P2. The nucleic acid sequence comprises the nucleotide sequence of N1, a fully defined sequence of 1518 (N2) or 9100 (N3) base pairs given in the specification, a codon 225 variant of the sequence of N1 or N3, or a nucleotide sequence corresponding to the mouse Prkag3 gene. The regulatory element is a muscle specific regulatory element, such as a myosin light chain promoter, a myosin heavy chain promoter, a skeletal alpha actin promoter, a creatine kinase promoter, or an aldolase A promoter. **Preferred Method:** In making a transgenic non-human animal, the expression construct is microinjected into the ovum or embryo, or into embryonic stem cells, of the non-human animal. The expression construct is electroporated into the embryonic stem cells. In identifying a compound or composition for treating or preventing a disease related to energy metabolism, the tissue is skeletal muscle and the cells are muscle cells.

ACTIVITY - Antidiabetic; Anorectic; Antilipemic. No biological data given.

MECHANISM OF ACTION - None given.

USE - The transgenic non-human animals are useful as models for improving treatment, prevention or diagnosis of diseases related to energy metabolism, or for identifying a compound or composition for treating or preventing a disease related to energy

metabolism, e.g. obesity, dyslipidemia, insulin resistance syndrome, or type 2 diabetes. The expression constructs are useful for making transgenic non-human animals. (46 pages)

AB The PRKAG3 gene encodes a muscle-specific isoform of the regulatory gamma subunit of AMP-activated protein kinase (AMPK). A major part of the coding PRKAG3 sequence was isolated from horse muscle cDNA using reverse-transcriptase (RT)-PCR analysis. Horse-specific primers were used to amplify genomic fragments containing 12 exons. Comparative sequence analysis of horse, pig, mouse, human, Fugu, and zebrafish was performed to establish the exon/intron organization of horse PRKAG3 and to study the homology among different isoforms of AMPK gamma genes in vertebrates. The results showed conclusively that the three different isoforms (gamma1, gamma2, and gamma3) were established already in bony fishes. Seven single nucleotide polymorphisms (SNPs), five causing amino acid substitutions, were identified in a screening across horse breeds with widely different phenotypes as regards muscle development and intended performance. The screening of a major part of the PRKAG3 coding sequence in a small case/control material of horses affected with polysaccharide storage myopathy did not reveal any mutation that was exclusively associated with this muscle storage disease. The breed comparison revealed several potentially interesting SNPs. One of these (Pro258Leu) occurs at a residue that is highly conserved among AMPK gamma genes. In an SNP screening, the variant allele was only found in horse breeds that can be classified as heavy (Belgian) or moderately heavy (North Swedish Trotter, Fjord, and Swedish Warmblood) but not in light horse breeds selected for speed or racing performance (Standardbred, Thoroughbred, and Quarter horse) or in ponies (Icelandic horses and Shetland pony). The results will facilitate future studies of the possible functional significance of PRKAG3 polymorphisms in horses.

AB The PRKAG3 gene encodes the gamma3 chain of AMP-activated protein kinase (AMPK). A non-conservative missense mutation in the PRKAG3 gene causes a dominant phenotype involving abnormally high glycogen content in pig skeletal muscle. We have determined >126 kb (in 13 contigs) of porcine genomic sequence surrounding the PRKAG3 gene and the corresponding mouse region covering the gene. A comparison of these PRKAG3 sequences and the human sequence was conducted and used to predict evolutionarily conserved regions, including regulatory regions. A comparison of the human genomic sequence and a porcine BAC sequence containing the PRKAG3 gene, revealed a conserved organization and the presence of three additional genes, CYP27A1 (cytochrome P450, family 27, subfamily A, polypeptide 1), STK36 (Serine Threonine Kinase 36), and the homolog of the unidentified human mRNA KIAA0173. Interspersed repetitive elements constituted 51.4 and 38.6% of this genomic region in human and pig, respectively. We were able to reliably align 12.6 kb of orthologous repeats shared between pig and human and these showed an average sequence identity of 72.4%. Our analysis revealed that the human KIAA0173 gene harbors alternative 5' untranslated exons originating from repetitive elements. This provides an obvious example how transposable elements may affect gene evolution.

AB An isolated DNA (I) of 15 bp is claimed. (I) contains a gamma3 subunit of human AMP-activated protein-kinase (PRKAG3) sequence, containing a nucleotide sequence variant and nucleotides flanking the sequence variant. Also claimed are: determining (M1) a risk estimate of a metabolic disease in a subject; detecting (M2) a PRKAG3 protein variant in a subject; and an article of manufacture containing a substrate and an array of different DNA immobilized on the substrate. (M1) is useful in determining a risk estimate of a metabolic disease which is a diabetes or obesity in a subject, and (M2) is useful for detecting PRKAG3 protein variant in a subject. (25pp)

AB The poorly developed transcript maps and the limited resources for genome analysis hamper positional cloning of trait loci in farm animals. This study demonstrates that this will now be easier by the combined use of BAC contigs and the import of the near complete human transcript map. The conclusion was obtained by a comparative analysis of a 2.4-Mb BAC contig of the RN region in pigs. The contig was constructed as part of a successful positional cloning project, which identified PRKAG3 as the causative gene for the RN phenotype. A comparative map including the corresponding regions on human chromosome 2q35 and mouse chromosome 1 (region 36-44 cM) is reported. Sixteen coding sequences were mapped on the BAC contig. The majority of these were identified by BLAST searches of BAC end sequences and BAC shotgun sequences generated during the positional cloning project. Map data for the orthologues in humans were available for 12 of the 16 coding sequences, and all 12 have been assigned to 2q35. Furthermore, no evidence for any rearrangement in gene order was obtained. The extensive linkage conservation indicates that the near complete human transcript map will be an invaluable resource for positional cloning projects in pigs and other domestic animals.

FILE SEGMENT: Priority Journals

ENTRY MONTH: 200005

ENTRY DATE: Entered STN: 6 Jun 2000
Last Updated on STN: 6 Jun 2000
Entered Medline: 25 May 2000

AB A high proportion of purebred Hampshire pigs carries the dominant RN-mutation, which causes high glycogen content in skeletal muscle. The mutation has beneficial effects on meat content but detrimental effects on processing yield. Here, it is shown that the mutation is a nonconservative substitution (R200Q) in the PRKAG3 gene, which encodes a muscle-specific isoform of the regulatory gamma subunit of adenosine monophosphate-activated protein kinase (AMPK). Loss-of-function mutations in the homologous gene in yeast (SNF4) cause defects in glucose metabolism, including glycogen storage. Further analysis of the PRKAG3 signaling pathway may provide insights into muscle physiology as well as the pathogenesis of noninsulin-dependent diabetes mellitus in humans, a metabolic disorder associated with impaired glycogen synthesis.
